

Spørsmål

Kan vi finne

1. tidlige risikofaktorer

2. tidlig effekt av trening?

TH: Nyborg Strand 2012 II

1

Prosjektets to deler

- 5 - 8 år:
- Effekt av trening

- 5 -12 år:
- Hvem utviklet dysleksi?

TH: Nyborg Strand I

2

Is it possible to identify dyslexia at a preliteracy phase?

- "Wait and see"
- "Could be stigmatising"
- "His father was like this, too"
- "She just doesn't pay attention"
- No, don't!
- Better to fail in school?
- Yes, it runs in families
- Have you asked yourselves why?

TH: Nyborg Strand 2012 II

3

Ti forskjellige publikasjoner om dysleksi - du vil møte ti forskjellige definisjoner!

- Hvorfor?
 - Flere årsakskjeder, - ikke bare én, et spektrum (Pennington & Bishop, 2009)
- BDA sin definisjon
- Hvordan skal en greie å få best innsikt?

- Longitudinelle studier (Dehaene, 2009; Goswami, 2003)

British Dyslexia Association sin definisjon av dysleksi:

- affects the development of literacy and language related skills
- present at birth and to be lifelong in its effects.
- characterised by difficulties with
 - phonological processing
 - rapid naming
 - working memory
 - processing speed
 - automatic development of skills that may not match up to an individual's other cognitive abilities.
- It tends to be resistant to conventional teaching methods, but its effects can be mitigated by appropriately specific intervention, including the application of information technology and supportive counselling.

4

Longitudinelle studier

(Dahaene, 2009; Goswami, 2008)

- Alle longitudinelle studier som har tatt utgangspunkt i førskolebarn og som til nå er publiserte er baaserte på genetikk/arvelighet som en tidlig risikofaktor (H. Lyytinen et al., 2004).
- Ikke alle barn av dyslektiske foreldre får dysleksi
- Ikke alle dyslektiske barn har dysleksi i den nærmeste familien
- Derfor er det nødvendig å definere andre risikofaktorer i tillegg til de genetiske
- De etablerte teoriene om dysleksi peker mot flere testbare risikofaktorer

TH: Nyborg Strand 2012 II

5

Longitudinelle studier eneste farbare vei, men hvordan?

Medfødt vanske

- forekomst ca 5 – 10%

Genotype:

- Barn av foreldre med dysleksi
 - kan følges fra fødsel av
 - mellom 30-70% har ikke "arvet" dysleksi

Fenotype:

- Personer med typiske kjennetegn på dysleksi
 - når kan vi "se" disse kjennetegnene?
 - vente å se, eller ta tidlige tegn på alvor?

TH: Nyborg Strand 2012 II

Dyslexia...

Congenital developmental disorder

- affecting aspects of **language**
- prevalence:
 - 5-10% (Siegel, 2006)
 - 5-17% (Shaywitz & Shaywitz, 2005)

Main focus over the last decades:

- **phonological processing** problems
- the **dyslexia spectrum**

(Vellutino, Fletcher, Snowling, & Scanlon, 2004)

Benchmark causal and contributing factors

- **heredity** (Grigorenko et al. 1997)
- **impaired language development** (Korkman & Häkkinen-Riihu 1994; Bishop 1997; Tallal 2000)
- the **magnocellular system** (Stein & Walsh, 1997)
- **abnormal laterality** (Geschwind 1979; Galaburda 1993)
- abnormal **motor control** (Nicolson & Fawcett, 1999)

In addition: **general health**
 Fox, S. E., Levin, P., & Nelson III, C. A. (2010). How the Timing and Quality of Early Experiences Influence the Development of Brain Architecture. *Child Development*, 81(1), 28-40.

...cannot be explained by one factor alone
 (Snowling, 2008; Pennington & Bishop, 2009)

7

Utfordringer

- **LI, RD, and SSD are complex multifactorial disorders**, not only in terms of their genetic and environmental etiology, but also in terms of their cognitive underpinnings.
- Each disorder appears to **arise as the consequence of a specific constellation of underlying deficits**.
- Each individual deficit may be common in the general population and **may only assume clinical significance when combined with another deficit**.

- It is estimated that to identify all of the **weakest 10%** of beginning readers, current measures would identify **20%** of children as being at high risk.
- Because effective prevention is resource-demanding, **more accurate identification** of at-risk children would be valuable.

The Risk Index (RI-5)

- 6 domains: soma, laterality, motor, language, spec. ed., heredity
- Filled out by parents and preschool teachers
- Sum scores averaged (parents, teachers)
- RI-5 formula:
 - Summed scores / (6 x 2) x 100
- Mean 9.96, SD 10.07 (range 0 – 47.5)
- Risk group: upper quartile of the RI-5
 - skewed gender profile, with few girls

Predicting Dyslexia at Age 11 from a Risk Index Questionnaire at Age 5

Turid Helland^{1*}, Elena Planes² and Kenneth Hugdahl^{1,3}

¹Department of Biological and Medical Psychology, University of Bergen, Norway
²Department of Speech, Language, and Hearing Sciences, University of Arizona, USA
³Division of Psychiatry, Haukeland University Hospital, Bergen, Norway

This study focused on predicting dyslexia in children ahead of formal literacy training. Because dyslexia is a constitutional impairment, risk factors should be seen in preschool. It was hypothesized that data gathered at age 5 using questions regarding the dyslexia endophenotype should be reliable and valid predictors of dyslexia at age 11. A questionnaire was given to caregivers of 120 5-year-old children, and a risk index score was calculated based on questions regarding health, laterality, motor skills, language, special needs education and heredity. An at-risk group (n = 25) and matched controls (n = 24) were followed until age 11, when a similar questionnaire and literacy tests were administered to the children who participated in the follow-up study (22 at risk and 20 controls). Half of the at-risk children and two of the control children at age 5 were identified as having dyslexia at age 11 (8 girls and 5 boys). It is concluded that it is possible to identify children at the age of 5 who will have dyslexia at the age of 11 through a questionnaire approach. Copyright © 2011 John Wiley & Sons, Ltd.

T. Helland et al.

Table 5. Predictive model of 1000 randomly sampled 5-year-old preschoolers

True positive 124 (12.38%)	False positive 29 (2.86%)
False negative 19 (1.9%)	True negative 829 (82.86%)

Clinical implications of the results point to a simple method of finding preschool children at risk of developmental dyslexia. If the low range RI-5 scores (17.01 for boys and 9.72 for girls) are used in a clinical situation, one should be especially aware of children with RI-5 scores in the range between these two cut-offs to avoid false negatives. In a research setting, it would be of interest to use the lowest range scores of the defined dyslexia group as cut-off scores because these scores would reduce the number of false positives and give a more accurate identification rate closer to the 10% as suggested by Gabrieli (2009). Table 5 shows the percent of children at age 5 who would be identified as having dyslexia through a general screening with this instrument, the percentage identified as typical, as well as the percent of false positive and false negative identifications.

This would yield a sensitivity measure of the RI-5 of .87 and a specificity measure of .87. Given the cost in time to administer the survey, these numbers suggest that the RI-5 could be a relatively efficient method of identifying children who would benefit additional assistance to develop reading skills.

In conclusion, this calculation is promising as to early identification of children at risk of dyslexia. Finding these children ahead of school age could open for interventions during the period when children are expected to be most sensitive to literacy training. However, replication studies on the RI-5 index and gender profiles in dyslexia research are necessary to validate the findings presented in this paper.
